# Comparison on the behavior of confined masonry structures made with ceramic vertical hollow blocks in correlation with CR6-2013 and P2-85 design codes requirements 

Daniel Stoica ${ }^{1}$, Mihai Niste ${ }^{2}$<br>${ }^{1}$ Associate Professor, PhD, Technical University of Civil Engineering, Faculty of Civil, Industrial and Agricultural, e-mail: stoica@utcb.ro, Romania<br>${ }^{2}$ Assistant Professor, Technical University of Civil Engineering, Faculty of Civil, Industrial and Agricultural, e-mail: mihainiste@yahoo.com, Romania

#### Abstract

Considering the provisions of the new design codes P100/1-2013 and CR62013 in this paper a comparison between structural responses for a building with structural masonry walls made of vertical hollow ceramic blocks calculated according to CR6-13 and P2-85 design codes requirements.

Keywords: Hollow, blocks, CR6-13, P2-85

## 1. Computation hypothesis

There has been realized two study cases for a building with 3 levels with confined masonry structure, having the dimensions in plan about 16.35 m with 8.85 m and the levels height of 2.75 m . As a location Bucharest was considered which is characterized by a peak ground acceleration $\mathrm{a}_{\mathrm{g}}=0.30 \mathrm{~g}$ and with the control period (corner period) $\mathrm{T}_{\mathrm{c}}=1.6$ seconds.
For the first study case computation vertical hollow ceramic blocks were considered; for the external walls the thickness $t=30 \mathrm{~cm}$ respectively for the interior walls $t=25 \mathrm{~cm}$. The specific weight of the masonry was considered $1050 \mathrm{kgf} / \mathrm{m}^{3}$. The masonry is made with a general purpose masonry mortar M5 and ceramic blocks with a standardized compression strength $\mathrm{f}_{\mathrm{b}}=10 \mathrm{~N} / \mathrm{mm}^{2}$, resulting the compressive strength of masonry $\mathrm{f}_{\mathrm{k}}=3.65 \mathrm{~N} / \mathrm{mm}^{2}$ according to Table 4.2.b of CR6-2013 code.
For the second study case were considered the same geometrical and weight ceramic blocks. The masonry is made with a general purpose masonry mortar M5 (M50 according $\mathrm{R}=2.30 \mathrm{~N} / \mathrm{mm}^{2}$ (see table 3 of STAS 10109/1-82), shear resistance $\mathrm{R}_{\mathrm{f}}=0.16$ $\mathrm{N} / \mathrm{mm}^{2}$ and characteristic strength for the main stretching efforts $\mathrm{R}_{\mathrm{p}}=0.11 \mathrm{~N} / \mathrm{mm}^{2}$ (see table 5 of STAS 10109/1-82).
For both study cases were determined the loads, level weights and the seismic base coefficient.

- The maximum ordinate for the elastic spectrum $\beta_{0}=2.50$;
- The reduction factor for buildings with more than 2 levels $\lambda=0.85$;
- The reduction factor which take into account the masonry critical damping ( $\xi=8 \%$ ) is $\eta=0.88$;
- The importance-exposure factor is $\mathrm{y}_{\mathrm{le}}=1.0$ (current building type according to table 4.2 from P100-1/2013 code;
- The behavior factor $\mathrm{q}=2.0$ (according to paragraph 8.3.4(5) from code P1001/2013);
- The global seismic coefficient $c=\gamma_{I e} \frac{\beta_{0} \times \lambda \times \eta}{q} \times \frac{a_{g}}{g}=1.0 \times \frac{2.5 \times 0.85 \times 0.88}{2} \times$ $\frac{0.30 g}{g}=0.28$
- There was also calculated the horizontal levels seismic forces as $F_{i}=$ $F_{b} \frac{m_{i} \times z_{i}}{\sum_{j=1}^{n} m_{j} \times z_{j}}$ (according to equation 4.5 from P100-1/2013 code).

## 2. Establishing the 2D models for seismic computation

The building shows geometric and structural symmetry in the plan and meets also the elevation conditions of regularity. It can be used to calculate it the equivalent static seismic forces using two planar models; building - regardless of the used blocks type fit into the type 1.1 (Table 5.1. from CR6-2013 code). The two models are illustrated below:

Comparison on the behavior of confined masonry structures made with ceramic vertical hollow blocks in correlation with CR6-2013 and P2-85 design codes requirements

Checking the structural walls density

| Transverse | Longitudinal |
| :---: | :---: |
| $\begin{gathered} \text { Ax } 1+\text { Ax } 5 \Rightarrow 2 \times(4.55 \times 0.30+2.55 \mathrm{x} \\ 0.30)=4.26 \mathrm{~m}^{2} \end{gathered}$ | $A x A+A x C=>2 \times(2 \times 0.3 \times 2.175+3 x$ |
| $\begin{gathered} \operatorname{Ax} 2+\operatorname{Ax} 4 \underset{ }{\Rightarrow} 2 \mathrm{x}(3.40 \times 0.25+3.40 \mathrm{x} \\ 0.25)=3.40 \mathrm{~m}^{2} \end{gathered}$ | Ax B $\quad=>2 x 0.25 \times 3.30+0.25 \mathrm{x}$ $7.75=3.5875 \mathrm{~m}^{2}$ |
| $2.2125 \mathrm{~m} 2$ $\text { Total } \quad \begin{aligned} & \Rightarrow \mathrm{A}_{\text {walls }}=9.8725 \mathrm{~m}^{2} \\ =>\mathrm{p} & =6.82 \% \end{aligned}$ | $\text { Total } \quad \begin{aligned} \quad & \Rightarrow \mathrm{A}_{\text {walls }}=10.6975 \mathrm{~m}^{2} \\ & \Rightarrow \mathrm{p}=7.39 \% \end{aligned}$ |

According to Table 8.9 from P100-1/2013 code for a 3 levels building located in a site with the $\mathrm{a}_{\mathrm{g}}=0.30 \mathrm{~g}$, the minimum density of structural walls is $\mathrm{p}_{\text {min }}=6.0 \%$ for confined masonry structural system.
There were checked each wall $\rho$ ratio (between the openings length and fullness masonry length according to table 8.11 of $\mathrm{P} 100-1 / 2013$ code - checking were done for a site with horizontal design acceleration $\mathrm{a}_{\mathrm{g}}=0.30 \mathrm{~g}$. Requirements: exterior walls $\rho \leq 0.8$, interior walls $\rho \leq 0.25$ respectively.

| Transverse | Longitudinal |
| :---: | :---: |
| $\begin{aligned} & \text { Ax } 1 \text { sau Ax } 5 \quad \Rightarrow l_{\text {openings }}=1.75 \mathrm{~m} \\ & 1_{\text {masonry }}=7.10 \mathrm{~m} \\ & \quad=>\rho=0.246 \leq 0.80 \text { (exterior walls) } \end{aligned}$ | $\begin{aligned} & \text { Ax A sau Ax C } \quad \Rightarrow l_{\text {openings }}=4.50 \mathrm{~m} \\ & 1_{\text {masonry }}=11.85 \mathrm{~m} \\ & \quad=>\rho=0.38 \leq 0.80 \text { (exterior walls) } \end{aligned}$ |
| $\begin{aligned} & \text { Ax } 2 \mathrm{sau} \mathrm{Ax} 4 \quad=>1_{\text {openings }}=1.80 \mathrm{~m} 1_{\text {masonry }} \\ & =7.05 \mathrm{~m} \end{aligned}$ | $\begin{aligned} & \text { Ax B } \\ & 1_{\text {masonry }}=14.35 \mathrm{~m} \end{aligned} \Rightarrow 1_{\text {openings }}=2.00 \mathrm{~m}$ |
| $\Rightarrow>\rho=0.25 \leq 0.25$ (interior walls) | $\Rightarrow>\rho=0.14 \leq 0.25$ (interior walls) |

The conditions from code P100-1/2013 - Table 8.11 are satisfied.
Structural analysis models take into account the connections made between the wall (cantilevers), which are made at every level by rigid floors (horizontal diaphragms) in their plan. In this case, the shear distribution between the structural walls stemming
came from the lateral displacement compatibility condition of the walls at each floor. Spandrels effect is negligible.
The connections between the walls were modeled as compressed strut articulated at both ends.
The walls were modeled as elastic rectangular bar (with respective values of the area, the shear area and moment of inertia) at the $\pm 0.00$ fixed support.
With this model from the equal condition translational displacements using a computer program for 2D analyses were calculated the sectional efforts (shear and bending moment) on each wall.

Because the torsion components depend only on the geometry and geometric properties of the walls, their values were considered proportional to those obtained by the method of independent cantilevers.

The calculation scheme for compressed struts
Design values of shear and bending moment for each wall are given in the below tables (for the transverse walls the values include increases from the torsional effect).

| First level pier | Positive sense seismic action |  |  |
| :---: | :---: | :---: | :---: |
|  | $\mathrm{V}_{\text {Ed }}$ | MEd | $\mathrm{V}_{\mathrm{Ed}} / \mathrm{ME}_{\mathrm{E}}$ |
|  | tf | tfm | d |
| T1 | 22. 4 | $\begin{gathered} 136 . \\ 8 \end{gathered}$ | 0.164 |
| T2 | 10. 1 | 54.7 | 0.185 |
| T3 | 10. 6 | 64.8 | 0.164 |
| T4 | 34. 5 | 265. 7 | 0.130 |

Transverse (including the torsional effects)

| First level pier | Positive sense seismic action |  |  |
| :---: | :---: | :---: | :---: |
|  | $\mathrm{V}_{\mathrm{Ed}}$ | MEd | $\mathrm{V}_{\mathrm{Ed}} /$ |
|  | tf | tfm | $\mathrm{MEd}^{\text {d }}$ |
| L1 | 8.0 | 45.5 | 0.176 |
| L2 | 9.7 | 58.8 | 0.165 |
| L3 | 9.7 | 58.7 | 0.166 |
| L4 | 9.8 | 64.2 | 0.153 |
| L5 | 30.8 4 | 284. 9 | 0.107 |

Longitudinal (neglected torsional effects)
Further structural safety checks will be carried out using values obtained by applying the cantilever sectional efforts attached to each level.

Conclusions available for the masonry structure made of ceramic blocks according to design code CR6-2013.

The requirement of structural resistance to compression and bending is satisfied for the whole building both directions.

* Transversely the T1 wall has insufficient strength $\mathrm{M}_{\mathrm{Rd}}=0.94 \mathrm{M}_{\mathrm{Ed}}$. Since this strength is less than $15 \%$, it is acceptable that the difference is covered by redistributing the total resistance $\Sigma \mathrm{M}_{\mathrm{Rd}}=1.15 \Sigma \mathrm{M}_{\mathrm{Ed}}$

## 5. The structural walls design shear strength computation

## Failure mechanism by sliding in horizontal beds

The design slip strength in horizontal beds of confined masonry walls, $\mathrm{V}_{\mathrm{Rd}}$ is calculated by adding:

- The design slip strength in horizontal beds of URM masonry panel corrected to take into account the effect of confinement elements ( $\left.\mathrm{V}_{\mathrm{RdI}} *\right)$;
- The design shear strength of reinforcement corresponding to compressed belt column from the compressed wall edge ( $\mathrm{V}_{\mathrm{Rd} 2}$ );
- The design shear strength of compressed belt column ( $\mathrm{V}_{\mathrm{Rsc}}$ ).

$$
\mathrm{V}_{\mathrm{Rd}}=\mathrm{V}_{\mathrm{Rd} 1} *+\mathrm{V}_{\mathrm{Rd} 2}+\mathrm{V}_{\mathrm{Rsc}} \text { according to relation (6.35) from CR6-2013 }
$$

$\mathrm{V}_{\mathrm{RdI}} *$ corrected strength calculation was made using the equation:

Comparison on the behavior of confined masonry structures made with ceramic vertical hollow blocks in correlation with CR6-2013 and P2-85 design codes requirements
$\mathrm{V}_{\mathrm{Rd}, \mathrm{l}}^{*}=\frac{1}{\gamma_{\mathrm{M}}} \mathrm{f}_{\mathrm{vk} 0} \mathrm{tl}_{\mathrm{ad}}+0.4 \mathrm{~N}_{\mathrm{Ed}}^{*}$ according to relation (6.35a) from CR6-2013
where $N_{E d}^{*}=N_{E d}+0.8 V_{E d} \frac{h_{\text {pan }}}{1_{\text {pan }}}$ according to relation (6.35b) from CR6-2013 $h_{\text {pan }}$ and $l_{\text {pan }}$ are the confined masonry panel dimensions.

In the following tables there used the notations:

$$
\mathrm{V}_{\mathrm{ad}}=\frac{1}{\gamma_{\mathrm{M}}} \mathrm{f}_{\mathrm{vk} 0} \mathrm{tl}_{\mathrm{ad}} \quad \mathrm{~V}_{\mu}=0.4 \mathrm{~N}_{\mathrm{Ed}}^{*}
$$

The compressed belt column reinforcement shear strength where computed according to CR6-2013, where for the longitudinal reinforcement of $Ø 14 \mathrm{f}_{\mathrm{yd}}=300 \mathrm{~N} / \mathrm{mm}^{2}, 2^{\text {nd }}$ strength category, and the stirrups of $\emptyset 8 \mathrm{f}_{\mathrm{yd}}=210 \mathrm{~N} / \mathrm{mm}^{2}, 1^{\text {st }}$ strength category, it was considered a $\lambda \mathrm{c}=0.25$ (table 6.3 from CR6).

$$
\mathrm{V}_{\mathrm{Rd} 2}=\lambda_{\mathrm{c}} \mathrm{~A}_{\mathrm{asc}} f_{\mathrm{yd}} \text { according to relation (6.36) from CR6-2013 }
$$

The shear strength value for the belt column concrete where computed with:
$\mathrm{V}_{\mathrm{Rsc}}=\mathrm{A}_{\text {bsc }} \times \mathrm{f}_{\text {cvd }}$ according to relation (6.37) from CR6-2013
$\mathrm{f}_{\mathrm{cvd}}=\mathrm{f}_{\mathrm{cvk}} / \mathrm{YC}_{\mathrm{C}}=0.27 \mathrm{~N} / \mathrm{mm}^{2} / 1.5=0.18 \mathrm{~N} / \mathrm{mm}^{2}$ ( concrete class C12/15 according to table 3.2 from EC 6 )

It result the total shear strength of the compressed belt column as: $V_{\text {Rstc }}=V_{\text {Rd2 }}+V_{\text {Rsc }}$

## Failure mechanism in inclined section

The design strength for inclined failure mechanism for the confined masonry walls ( $\mathbf{V}_{\mathbf{R d}}$ ) is computed by assuming:

- The design strength for inclined section of a URM masonry panel corrected to take into account the interaction with the confinement elements (VRdi*);
- The design shear strength due to compressed belt column reinforcement from the compressed wall edge (VRd2);
- The design shear strength for the compressed belt column (VRsc).

$$
\text { VRd }=\text { VRdi* }+ \text { VRd2 }+ \text { VRsc }
$$

The $\mathrm{V}_{\mathrm{Rd} 2}$ and $\mathrm{V}_{\mathrm{Rsc}}$ values are identical with those determined for the horizontal slip mechanism.
Characteristic tension strength of burned clay elements were considered as: $f_{b t}=$ $0.035 f_{b}$ according to (4.5a) from CR6-2013
Standardize compression strength of burned vertical hollowed clay blocks were considered: $\mathrm{f}_{\mathrm{b}}=10 \mathrm{~N} / \mathrm{mm}^{2}$
Resulting that: $\quad f_{b t}=0.035 f_{b}$ so $\quad f_{b t}=0.035 \times 10 \mathrm{~N} / \mathrm{mm}^{2}=0.35 \mathrm{~N} / \mathrm{mm}^{2}$
Characteristic unitary inclined strength for ceramic masonry where computed by:

$$
f_{v k, i}=0.22 f_{b t} \sqrt{1+5 \frac{\sigma_{d}^{*}}{f_{b t}}}=0.077 \sqrt{1+14.285 \sigma_{d}^{*}} \quad \text { according to (4.4a) from }
$$

CR6-2013
The design inclined strength became:
$V_{R d, i}=\frac{A_{w}}{b} \times \frac{f_{v k, i}}{\gamma_{M}}=\frac{A_{w}}{b} \times f_{v d, i}$ according to (6.34) from CR6-2013
b - correction coefficient that takes into account the aspect ratio of the masonry panel
$\mathrm{b}=1.5$ for $\mathrm{h} / \mathrm{l}_{\mathrm{w}} \geq 1.5$
$\mathrm{b}=1.0$ for $\mathrm{h} / \mathrm{l}_{\mathrm{s}}<1.0$
$\mathrm{b}=\mathrm{h} / \mathrm{l}_{\mathrm{w}}$ for $1.0 \leq \mathrm{h} / \mathrm{l}_{\mathrm{w}}<1.5$ according to 6.6.4.1.2. from CR6-2013
$\mathrm{h}=\mathrm{H}_{\text {tot }}$ for all the cantilever walls $=>\mathrm{H}_{\text {tot }}=8.25 \mathrm{~m}$
The values $\mathrm{V}_{\text {Rdi* }}$ and the confined masonry inclined strength appear in the following tables:

## Associated shear force for bed joints reinforcement

The shear force taken by the horizontal bed joints reinforcements is calculated using the equation: $V_{R d 3}=0.81_{w} \frac{A_{s w}}{s} f_{y d}$ according to (6.41) from CR6-2013. In the case of ceramic with vertical hollow masonry block with reinforcement in the horizontal bed joints will be with OB37 208 and $\mathrm{f}_{\mathrm{yd}}=210 \mathrm{~N} / \mathrm{mm}^{2}\left(\mathrm{Asw}=100.48 \mathrm{~mm}^{2}\right)$ from two rows on the $1^{\text {st }}$ floor $\mathrm{s}=2 \times 250 \mathrm{~mm}=500 \mathrm{~mm}$, respectively at the $2^{\text {nd }}$ and $3^{\text {rd }}$ floor from row to rows $\mathrm{s}=250 \mathrm{~mm} . \mathrm{V}_{\mathrm{Rd}}(\mathrm{ZC})=\min \left(\mathrm{V}_{\mathrm{Rd}, 1} ; \mathrm{V}_{\mathrm{Rd}, \mathrm{i}}\right)$ and $\mathrm{V}_{\mathrm{Rd}}(\mathrm{ZC}+\mathrm{AR})=\mathrm{V}_{\mathrm{Rd}}(\mathrm{ZC})+\mathrm{V}_{\mathrm{Rd}, 3}$

| L1 | 1.13 | 1.22 |
| L2 | 1.17 | 1.31 |
| L3 | 1.17 | 1.31 |
| L4 | 1.14 | 1.28 |
| L5 | 1.27 | 1.68 |
| Average ratio for longitudinal direction | 1.17 | 1.36 |
| Average ratio for both directions | 1.16 | 1.34 |
| Total average ratio | 1.25 |  |

So there is a noticeable difference in overall average of $25 \%$ in addition to values derived from calculations resilience made according to P2-85 and those completed under CR613.

It can be said that in terms of structural responses obtained that the CR6-2013 design code provides an increase of $25 \%$ versus safety requirements P2-85 former design code.

## 7. Using the pushover models

2 models were carried out for structural analysis, one for each type of structure (longitudinally or transverse direction).
After pushover analyses the base shear force-displacements curve were obtained:

The followings values may be observe:

- Transverse direction:
o $\mathrm{V}_{\mathrm{y}}=422.9 \mathrm{tf}$ and $\Delta_{\mathrm{y}}=4.44 \mathrm{~mm}$ respectively $\mathrm{V}_{\mathrm{u}}=449.2 \mathrm{tf}$ and $\Delta_{\mathrm{u}}=127.2 \mathrm{~mm}$
- Longitudinal direction:

$$
0 \quad \mathrm{~V}_{\mathrm{y}}=328.6 \mathrm{tf} \text { and } \Delta_{\mathrm{y}}=3.65 \mathrm{~mm} \text { respectively } \mathrm{V}_{\mathrm{u}}=376.6 \mathrm{tf} \text { and } \Delta_{\mathrm{u}}=124.2 \mathrm{~mm}
$$

- The differences between the both masonry direction structures are:

| Characteristic | Difference <br> between <br> longitudinal/ <br> transverse | Average for <br> characteristic |
| :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{y}}$ | $28.69 \%$ | $23.99 \%$ |
| $\mathrm{~V}_{\mathrm{u}}$ | $19.28 \%$ |  |
| $\Delta_{\mathrm{y}}$ | $21.64 \%$ | $12.03 \%$ |
| $\Delta_{\mathrm{u}}$ | $2.42 \%$ |  |

It can be seen that the average differences for the two directions (longitudinal and transverse) are approximately $23.99 \%$ between base shear forces and $12.03 \%$ between deflections.

## Ultimate plastic mechanisms

Transverse direction
Longitudinal direction

## 8. Conclusions

The safety for shear is satisfied on the whole building, ensuring the favorable energy dissipation mechanism by ranking seismic resilience of the structure used for the type of masonry (vertical hollow ceramic blocks). This can be seen both in the simplified calculations but also in pushover analysis.
Since confined masonry by some walls and some levels do not meet the requirement of shear safety, a reinforcement in the horizontal bed joints was considered made with $2 Ø 8$ OB37 (local $3 Ø 8$ OB37 in walls T4 $-3^{\text {rd }}$ floor and L5 $-1^{\text {st }}$ and $2^{\text {nd }}$ floor), arranged in two rows on the $1^{\text {st }}$ floor and on a rows for $2^{\text {nd }}$ and $3^{\text {rd }}$ floor. So finally, for both types of calculations were considered ZC + AR-type structure.

Using the simplified calculation models (structural regularity permitting the 2 D and elevation of the structure considered), leading to a structural conformation, neglecting a significant component show a computing collaboration on spatial structure.
The structural compliance can be optimized by the choice of models and methods for calculating the minimum allowed higher, applied in this paper.
To obtain a safe structural conformation under the seismic action and economic and functional optimal, were used models for nonlinear static behavior. To obtain more reliable results it is recommended structural models using 3D and modal calculation, to capture more accurately the real behavior of the structure.
It finds that structural responses obtained for the two types of calculations performed for masonry structure made with ceramic vertical hollow blocks are quite close even for normal or superior level analysis or different design strengths.
It can be said that in terms of structural responses obtained from CR6-2013 in force design code provides an increase of $25 \%$ safety versus the requirements of P2-85 former code.
